Introduction

Spontaneous spinal epidural hematoma (SEH) is an uncommon and emergency condition leading to spinal cord compression. Early diagnosis can be achieved by magnetic resonance imaging (MRI) or computed tomography, but preferably MRI. Surgical decompression is urgent and can relieve neurologic deficits. A 27-year-old man presented to the emergency department with back pain, which began approximately 10 days before. While waiting for the results of biological markers for differential diagnosis, right hemiplegia became evident. Epidural hematoma was revealed with thoracic and lumbar MRI at level T1-T2. Hematoma evacuation and decompression laminectomy was immediately performed.

Case Presentation

A 27-year-old man presented to the emergency department with back pain, which began about approximately 10 days before. While waiting for the results of biological markers for differential diagnosis, right hemiplegia became evident. Epidural hematoma was revealed with thoracic and lumbar MRI at level T1-T2. Hematoma evacuation and decompression laminectomy was immediately performed.
Discussion

Spontaneous SEH is an important clinical presentation for neurological emergency. Spontaneous SEH may appear due to epidural venous plexus favored by coagulation, hemangiomas, or spinal arteriovenous malformations (4).

Early detection of spontaneous SEH is difficult process due to atypical symptoms. Clinical symptoms suddenly occur, and neurological symptoms may vary (5). Most researchers claim that it occurs at the epidural venous plexus in the spinal epidural space of the thoracic spine, and the abdominal cavity can also be directly affected. However, Miyagi et al reported that arterial blood supply is a more persuasive force for pressure inside the venous plexus as it is lower than that in the epidural space. Furthermore, in some cases, rapidly deteriorating neurological deficits after the initial onset of back pain or lumbago indicated a rapid formation of the hematoma and spinal cord compression, which is suggestive of the arterial origin of spontaneous SEH (6).

Prompt diagnosis is difficult due to atypical symptoms, variations in age, and clinical suspicion is also difficult. Rapid diagnosis by MRI is pivotal because neurological symptoms are often severe (7). Although epidural hematomas are usually found on the posterior spinal cord in a lentiform shape, spontaneous SEHs are commonly observed on the anterolateral and around the spinal cord in a semi-circular pattern, accompanied with compression and some displacement (8).

Spontaneous SEH should be routinely considered in patients who have symptoms of spinal cord compression without other clinical findings. Spinal masses are frequently noticed during differential diagnosis. Definitive diagnosis is mostly achieved with operation. Not only are the findings of spontaneous SEH seen; furthermore, pathological evaluation is also required to diagnose lymphoma and metastasis. In addition, MRI findings of these conditions are similar to those of spontaneous SEH. Spontaneous SEH mostly occurs in the thoracic spine, usually extending over several vertebrae. The pathological specimen in our case was a hematoma. Surgical removal of the hematoma was inevitable in this case, although conservative treatment may be sufficient in some cases (9).

Our patient suffered from lumbar pain for approximately 10 days. Neurological examination was normal during the first evaluation of the patient. Oversensitivity of the spinal process and paravertebral line of the thoracic vertebrae was established. However, SEH should be considered by emergency physicians in the pre-diagnosis of patients with a variety of neurological complaints. Fortunately, the rapidly deteriorating neurological deficits during observation and the subsequent emergency neurosurgery intervention ensured smooth recovery for our patient.

Spontaneous SEH should be suspected in patients admitted with a common back pain in crowded emergency departments. Early diagnosis and timely management of spontaneous SEH may improve prognosis and outcome. In this case, MRI was vitally important as the patient presented with neurological symptoms following back pain.
